Received 1999 December 14; accepted 2000 January 15

342 CCD measurements of relative positions and magnitude differences for 145 visual double stars are presented. Observations were carried out at the 1.23m telescope of the German-Spanish Astronomical Center at Calar Alto (Spain), all of them in V and R photometric bands.

Key words: Visual double stars – CCD measurements: *V* and *R* band, separation, position angle, magnitude difference

1. Introduction

The CCD technique has revealed as a useful tool in astrometry and photometry of visual double stars, as it has been fully demonstrated in the recent years. A good evidence of that is, for example, the contribution of the European Network of Laboratories "Visual Double Stars" (Oblak *et al.*, 1999) where a detailed description of both intermediate and wide binaries observations based on 50 observing runs carried out in both hemispheres since 1991 is given.

In Spanish professional astronomy the double stars measurements are being performed mainly by the team of investigators from Astronomical Observatory "Ramón María Aller" and their collaborators. While the program is focused preferably on close binaries, the numerous micrometric and photographic observations of pairs with an angular separation of more than two arcsec have been performed both at the observational site in Santiago de Compostela and at the Centro Astronómico de Yebes (Observatorio Astronómico Nacional, Spain).

Since 1994 the scientific collaboration with the Center of Investigations in Astronomy (CIDA, Venezuela) allowed us to obtain the relative positions using the CCD measurements carried out with 1m telescope of Llano de Hato Observatory belonging to CIDA (Abad *et al.*, 1998). As its continuation we report here the measurements obtained in two observing runs in August and September of 1997 with the 1.23m telescope of the Spanish-German Center of Astronomy at Calar Alto (Almería, Spain). For simultaneous CCD astrometry and photometry of binary stars this telescope was first used eight years before by Sinachopoulos and Seggewiss (1990).

2. Observations and data reduction

The telescope has been equipped with TEK 6 1024×1024 pix CCD camera built into a Dewar filled liquid Nitrogen and cooled to -120°C . The pixel size is $24\mu\text{m}$ which is equivalent to $0.^{\prime\prime}502$ in the focal plane. The following filters have been used:

V	BG	18 (2mm)	+GG	495 (2mm)
R	OG	570 (2mm)	+KG	3 (2mm)

In total 145 program stars have been selected mainly because of few observations reported for these stars as well as some others because of a special interest. Hipparcos data (Perryman *et al.*, 1997) are known for 33 of them.

85 of the program stars have separations between 1 and 5 arcsec, 56 between 5 and 15 arcsec and 4 more than 15 arcsec. As regards the magnitude differences between components, 106 are between 0 and 1, 27 between 1 and 2 and 12 between 2 and 3.

Observations in R and V bands have been carried out for each star. The exposure time depends on the system brightness but in average it was about 20 seconds. Seeing conditions were moderately favorable, generally about 1''.5 - 2''.0.

The standard reduction procedure (flat field, bias, etc.) using MIDAS version 97NOV has been applied usually in ROMAPHOT (Bounanno *et al.*, 1983) environment. In order to resolve mostly overlapped stellar images the latter has been mainly used in semiautomatic mode.

Dark current of the camera may be neglected since it was very weak (a few counts per hour per pixel).

3. Results

In Table 1 data of 342 terms of position angle (θ), separation (ρ) and magnitude difference (Δm) values are presented. Each star is identified by its WDS number (Worley & Douglass, 1996), name (with the component letter, if any) and ADS number (Aitken, 1932). The next columns provide the observation epoch, the photometric passband letter, θ , ρ and Δm values. For the stars WDS 00255+6129, 19523+6222, and 20167+4335 the data on three components have been obtained. The letter H indicates the stars observed by Hipparcos while the stars having at least one calculated orbit are marked by an asterisk. For these latter stars we include in Table 2 the corresponding residuals with the orbits whose references are given too. The position angles measured with two filters differ in less than $0^{\circ}5$ for 137 measurements are between $0^{\circ}5$ and $0^{\circ}9$ for 9 of them and between $1^{\circ}0$ and $2^{\circ}5$ in just 16 cases. Regarding the angular distances, their difference is less than $0''.05$ in 149 cases, between $0''.06$ and $0''.1$ in 8 cases and is greater than $0''.1$ in 5 cases solely. The estimated errors are in order of $\pm 0^{\circ}4$ in position angle and $\pm 0''.03$ in separation.

Acknowledgements. We are grateful for the observing time allocation to the German-Spanish Astronomical Center which is operated by the Max-Planck-Institut für Astronomie (Heidelberg) jointly with the Spanish National Commission for Astronomy.

This work has been co-financed by the spanish institutions, Xunta de Galicia and DGES under investigation projects XUGA 24301B96, PGIDT 99PXI 24301B and PB 97-0514, respectively.
