#### Abstract

The enantiomerically pure ( $1 R, 2 R$ )- and ( $1 S, 2 S$ )-1-amino-2-phenylcyclohexane-1-carboxylic acids ( $\mathrm{c}_{6} \mathrm{Phe}$ ) 3a and 3b were synthesized in good yields by a resolution method described by Obrecht. This method involves the formation of the diastereoisomeric peptides $7 \mathbf{a}$ and 7 b followed by chromatographic separation. The free ( $1 R, 2 R$ )- and ( $1 S, 2 S$ )-c $\mathrm{c}_{6}$ Phe amino acids ( 3 a and 3 b ) were converted into appropriately protected phenylalanine analogues 10a and 10b for possible use in peptide synthesis. The conformational analysis, in solution, of these peptides revealed that dipeptide 3a shows an extended-type conformation, while dipeptide 3b shows a type I $\beta$-turn geometry. In addition, we have prepared the unsaturated peptides 11a and 11b and the structure of 11b, determined by X-ray analysis, also shows a type I $\beta$-turn conformation in the solid state. The NMR data of this dipeptide (11b) allowed the characterisation of the type I $\beta$-turn conformation in solution and established it to be similar to the solid state structure. These results suggest that $\mathrm{c}_{6}$ Phe can be used as building blocks to stabilise type $1 \beta$-turns or extended chains in peptides, depending on their absolute configurations. © 1998 Elsevier Science Ltd. ## Introduction

The conformational flexibility of peptides is one of the limitations of their use as drug leads. Because of this, in recent years, several conformationally restricted analogues of bioactive peptides (peptidomimetics) have been developed in order to establish a threedimensional structure-bioactivity relationship and to design new pharmacological agents with more selective properties than the original peptides [1]. There are a number of different approaches to the synthesis of conformationally restricted peptidomimetics at the amino acid level and, in this context, the systematic exchange of individual amino acids by the corresponding modified amino acid is well established [2]. For example, conformational restriction through $\mathrm{C}_{\mathrm{i}} \alpha_{\leftrightarrow} \mathrm{C}_{\mathrm{i}}{ }^{\alpha}$ cyclization generates the family of 1 -aminocycloalkane-1carboxylic acid $\left(\mathrm{Ac}_{\mathrm{n}} \mathrm{c}\right)$ residues and different studies of the preferred conformations of peptides characterised by the $A c_{n} c(n=3-9)$ residues have been the subject of recent reviews [3]. Moreover, it is known that certain cyclic $\alpha, \alpha$-disubstituted amino acids, notably those with $n=3,5$ and 6 , tend to induce $\alpha$-helical or $\beta$-turn conformations when they are incorporated into peptides.

## Synthesis of cyclic amino acid analogues of Phe: $\mathrm{c}_{6} \mathrm{Ph}$ he

As a part of our research project on the synthesis of new $\alpha$-amino acids with conformational rigidity and with the aim of contributing to the development of cyclic conformationally restricted amino acids, in particular analogues of phenylalanine (Phe), we have reported the synthesis of 1 -amino- $t$-2-phenylcyclohexane- $r$-1-carboxylic acid (3a,b) ( $\mathrm{c}_{6} \mathrm{Phe}$ ) in its racemic form [4] by the Diels-Alder reaction of ( $Z$ )-2-phenyl-4-benzyliden$5(4 \mathrm{H})$-oxazolone (1) and 1,3 -butadiene. In order to incorporate this $\mathrm{c}_{6} \mathrm{Phe}$ amino acid into peptides, we are interested in both enantiomers of this novel non-proteinogenic amino acid. In this context, we have recently published the asymmetric synthesis of $(1 R, 2 R)$ - and $(1 S, 2 S)$-1-amino-2-phenylcyclohexane-1-carboxylic acids (3a and 3b) [( $1 R, 2 R$ )- and ( $1 S, 2 S$ )-c6Phe] starting from the corresponding cycloadducts of the Diels-Alder reaction between 1,3butadiene and the chiral ( $E$ )-2-cyanocinnamates $\mathbf{5 a}$ and $\mathbf{5 b}$ as dienophiles, using ( $S$ )-ethyl lactate and ( $R$ )-pantolactone as chiral auxiliaries [5]. (Scheme 1).

Further transformations of the cyano and carboxylate groups of cycloadducts $\mathbf{4 a}$ and $\mathbf{4 b}$ into the corresponding amino and carboxylic acid groups allowed the synthesis of both enantiomerically pure amino acids, but only in $22 \%$ yield, from dienophiles. Nevertheless, these apparently simple transformations suffered from significant synthetic difficulties that produced a decrease in the yield of the amino acids and, consequently, the amino acids could not be obtained in an easy and quick way. Due to this fact, and encouraged by the excellent yield obtained in the synthesis of this racemic amino acid from the unsaturated $5(4 \mathrm{H})$ oxazolone, we decided to explore the scope of the asymmetric Diels-Alder reaction between the $5(4 \mathrm{H})$-oxazolone and 1,3 -butadiene using different chiral catalysts. Such a method has not previously allowed the successful synthesis of both stereoisomers. For this reason we have considered that, in this particular case, an efficient method for the resolution of the racemic ${ }_{6}$ Phe 3a,b is more practical than an enantioselective synthesis.

In this paper we present a very efficient strategy for resolution of racemic $\mathbf{c}_{6} \mathrm{Phe} \mathbf{3 a , b}$. This strategy was previously developed and reported by Obrecht to prepare and resolve both cyclic and acyclic $N$-acylated $\alpha, \alpha$-disubstituted amino acids [6]. The method is based on the formation of diastereoisomeric dipeptides, which are easily separated by column chromatography. Once separated, these diastereoisomers are selectively cleaved to give, in
high yield, the corresponding $N$-acylated amino esters. In our case, the synthesis of the two enantiomerically pure amino acid analogues of Phe started from the racemic Diels-Alder cycloadduct $2 \mathbf{a}, \mathbf{b}$. The double bond of this system was hydrogenated in the presence of palladium/carbon as a catalyst to obtain the racemic 2'-phenylcyclohexane-1-spiro-2-phenyl$5(4 \mathrm{H})$-oxazolone $6 \mathbf{a}, \mathrm{~b}$, which was smoothly reacted with L-phenylalanine cyclohexylamide in N -methylpyrrolidin-2-one (NMP) as a solvent, at $90^{\circ} \mathrm{C}$. The corresponding diastereoisomeric peptides 7a and 7b were obtained in good yields after silica gel column chromatography using hexane/ethyl acetate (7:3) as eluent. Each diastereoisomeric peptide 7a and 7b was separately treated with trifluoromethanesulphonic acid in MeOH at $80^{\circ} \mathrm{C}$ to give the optically pure methyl esters $\mathbf{8 a}$ and $\mathbf{8 b}$. Finally, hydrolysis of the benzamido and methyl ester groups with aqueous 6 N HCl at $100^{\circ} \mathrm{C}$ gave the optically pure $\mathrm{c}_{6} \mathrm{Phe}$ as chlorhydrate derivatives 9 a and 9 b . In order to assess the enantiomeric purity and determine the absolute configuration of each amino acid, these chlorhydrate derivatives were each dissolved in EtOH and propylene oxide was then added. After 2 hours at reflux, the free amino acids 3a and 3b were obtained and the observed optical rotations were in agreement with those described in the literature [5]. (Scheme 2).

## Protection of amino acids $\mathrm{c}_{6} \mathbf{P h e}$

The optically pure $\mathrm{c}_{6}$ Phe 3a and 3b are potentially interesting amino acids for incorporation into short peptides and, consequently, the corresponding amino acids with suitable protecting groups were required [7]. Indeed, it is advisable in peptide synthesis to dispose of the orthogonally doubly protected amino acids, so we chose the combination of the $N$-benzyloxycarbonyl group ( $N$-Cbz) with the allylic ester group. Firstly, the Cbz-protected amino acids were obtained using the Kricheldorf method [8], which is based on the addition of $\mathrm{Me}_{3} \mathrm{SiCl}$ (TMS-Cl) to the corresponding amino acid chlorhydrate derivatives $9 \mathbf{9}$ and $\mathbf{9 b}$. We then carried out the reaction with ${ }^{i} \mathrm{Pr}_{2} \mathrm{EtN}$ and benzyl chloroformate ( $\mathrm{Cbz}-\mathrm{Cl}$ ). The $\mathrm{Cbz}-$ protected $c_{6}$ Phe were not be purified, but were conveniently converted into the corresponding allyl esters by the action of DBU and allyl bromide in DMF to give, in high yield, the desired orthogonally doubly protected Phe analogues 10a and 10b. (Scheme 3).

## Conformational Analysis of dipeptides containing $\mathbf{c}_{6} \mathrm{Phe}$

In order to determine the interesting conformational aspects of dipeptides 7a and 7b, we first studied their conformational analysis in solution [9] and later in the solid state. The most representative proton resonance assignment in the ${ }^{1} \mathrm{H}$-NMR spectra of peptides 7 a and $\mathbf{7 b}$ was made on the basis of coupling constants, selective proton-proton homonuclear decoupling experiments, proton-proton COSY experiments and proton-carbon COSY experiments. The results of these studies are summarised in Table 1. Starting from the scalar couplings ${ }^{3} J_{\text {NHPhe- }} \alpha$ and applying the Karplus equation [10], using the parametrization of Pardi and coworkers [11], we obtained two possible values for the dihedral angles $\phi_{2}$ for every peptide. (Figure 1).

Figure 1

${ }^{\text {a }}$ The spectra were recorded in $\mathrm{CDCl}_{3}$ and TMS was used as the internal standard. The chemical shifts are reported in ppm on the $\boldsymbol{\delta}$ scale and coupling constants in Hz .

On the other hand, the analysis of ${ }^{3} J_{\alpha-\beta}$ in the Phe residue of both peptides provides information about the dihedral angle $\chi_{1}$. In particular, it is observed that in the peptide $7 \mathbf{a}$ there is more than one rotamer conformation ( $\mathrm{t} 2 \mathrm{~g} 3, \mathrm{~g} 2 \mathrm{t} 3$ and g 2 g 3 ) due to the conformational flexibility of the $-\mathrm{CH}_{2} \mathrm{Ph}$ side chain [12]. When the fractional populations t2g3, g2t3, g2g3 for three staggered rotamers about the $\mathrm{C}_{\alpha}-\mathrm{C}_{\beta}$ bond of Phe were calculated using the $J$-coupling for Pachler's equation [13], the average $\mathrm{P}_{\mathrm{x}}$-values obtained were 0.53 , $0.29,0.18$, respectively (the values of t 2 g 3 , and g 2 t 3 are interchangable). These values indicate that $53 \%$ of the rotamer population shows a dihedral angle $\chi_{1}$ of $60^{\circ}$ or $180^{\circ}$. Up to now it has been impossible to discriminate between these values, although Hruby [16a] reported that in short peptides the aromatic ring of the Phe residue adopts a position far removed from the main chain of the peptide. In the case reported here this corresponds to a $\chi_{1}$ value of $180^{\circ}$. (Figure 2).

In contrast, in peptide $7 \mathbf{b}$ the analysis of ${ }^{3} J_{\alpha-\beta}$ reveals that the $69 \%$ of the rotamer population shows a dihedral angle $\chi_{1}$ of $-60^{\circ}$, corresponding to the gauche-gauche (g2g3) conformation. (Figure 2).
Peptide 7a

Peptide 7b

Figure 2

By means of ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy we have studied the possible formation of hydrogen bonds in these systems. The presence of hydrogen-bonded NH resonances has usually been confirmed by measuring the degree of solvent exposure of each NH group in a given peptide [14]. In the present study, we have used the criterion of the solvent dependence of the NH chemical shifts in $\mathrm{CDCl}_{3} / \mathrm{DMSO}-\mathrm{d}_{6}$ mixtures. The NH resonances in peptides $7 \mathbf{a}$ and $\mathbf{7 b}$ could be assigned in a straightforward manner. The signals for NHCOPh appear as broad singlets at 6.29 and 6.35 ppm , respectively. On the other hand, NHCy appeared as doublets coupled with the H 1 ' protons of the cyclohexane ring, at relatively high field ( 5.27 ppm ) in peptide 7 a and at lower field ( 6.76 ppm ) in peptide 7 b . In the latter case this indicates the possible involvement of hydrogen bonding [15]. The remaining doublet NH resonances show coupling with $\mathrm{H}_{\alpha}$ of the Phe residue and this appeared in the peptides 7 a and 7 b at 6.66 ppm and 5.41 ppm, respectively.

As shown in Figure 3, the NHCy resonance in $\mathrm{CDCl}_{3}$ for peptide 7a was markedly shifted to a lower field upon adding the strong hydrogen-bond accepting DMSO-d $\mathrm{d}_{6}$ solvent. Nevertheless, the NHCOPh and NHPhe resonances were less affected by the addition of DMSO-d 6 . This fact indicates that NHPhe and NHCOPh have a solvent-shielded nature due to the presence of intramolecular hydrogen bonds. All the NH chemical shifts changed in a similar way up to DMSO- $\mathrm{d}_{6}$ concentrations of $40 \%(\mathrm{v} / \mathrm{v})$, suggesting that no major conformational change occurred in this experiment. The same experiment for peptide $7 \mathbf{b}$ shows that NHCy and NHPhe are involved in intramolecular hydrogen-bonds. (Figure 3).

Figure 3
In order to obtain further information concerning the main chain conformations, difference NOE experiments were carried out [16]. When the NHCy proton was irradiated in peptide 7 a , enhancements of $8 \%$ and $2 \%$ were observed in the $\mathrm{H}_{\alpha}$ and $\mathrm{H}_{1}$ ' protons, respectively. However, such an NOE enhancement was not observed in NHPhe. An NOE enhancement was also not observed in NHCy when NHPhe was presaturated. The most relevant NOE data observed in peptide 7b were those corresponding to the NHPhe (6\%) and $\mathrm{H}_{\alpha}(2 \%)$ protons when the proton NHCy was irradiated. These observed NOE enhancements suggest that the most probable values for the dihedral angles $\phi 2$ will be near to $-148.2^{\circ}$ in peptide 7a and to $-94.7^{\circ}$ in peptide 7b. (Figure 4).

Figure 4

Taking into account the fact that the above empirical information on dihedral angles of peptides, obtained from 1D-NMR experiments, is not sufficient to define a specific conformation, we have built the simple models using the INSIGHT II program based on NMR parameters. We have subsequently optimized these starting structures with the molecular mechanics force fields CVFF and CFF91 implemented in the above program [17].

The lowest energy conformations for peptides $\mathbf{7 a}$ and $\mathbf{7 b}$ correspond to the structures shown in Figure 4 and the distances and the dihedral angles are represented in Table 2. Peptide 7a, containing the ( $1 R, 2 R$ )- $\mathrm{c}_{6} \mathrm{Phe}$ residue, shows an extended-type conformation, while peptide 7b, $(1 S, 2 S)$-c 6 Phe, shows a type I $\beta$-turn. Both structures contain two hydrogen bonds [18].

In order to establish a comparison between the conformations that these peptides exhibit in solution and in the solid state, we attempted to crystallize them; however, we could not obtain monocrystals of dipeptides. In contrast, we could obtain the X-ray structure [19] of unsaturated peptide 11b, which also shows a type I $\beta$-turn structure (Figure 5). Peptide 11b was obtained from racemic unsaturated $5(4 \mathrm{H})$-oxazolone cycloadduct 2 a by reaction with L phenylalanine cyclohexylamide in NMP at $90^{\circ} \mathrm{C}$. The resulting unsaturated diastereoisomeric peptides 11a and 11b were separated by silica gel column chromatography eluting with hexane/ethyl acetate (7:3). (Scheme 4).

Figure 5

Scheme 4
The NMR spectra of the unsaturated peptide 11b, the NOE difference experiments and solvent accesibility ( $\mathrm{CDCl}_{3} / \mathrm{DMSO}-\mathrm{d}_{6}$ ) are similar to those obtained in the saturated peptide 7b with the same configuration (Figure 6). This starting structure was also optimized with the molecular mechanics force fields CVFF and CFF91 implemented in the INSIGHT II program. These results make it possible to compare both peptides of configuration ( $S, S, S$ ) and we could establish that both peptides have the same conformation in the solid state as in solution and are folded according to a type I $\beta$-turn with stabilizing intramolecular $\mathrm{i}+3 \rightarrow \mathrm{i}$ hydrogen bonds. Table 2 show the values of the dihedral angles for the residues $\mathrm{i}+1$ and $\mathrm{i}+2$ in peptides 7b and 11b. These values were obtained from the conformational analysis in solution and in the solid state, and the values of these angles are as one would expect for the ideal type I $\beta$-turn.

${ }^{\text {a }}$ Optimization using the cvff force field implemented in the Insight II program
${ }^{\text {b }}$ Optimization using the cff91 force field implemented in the Insight II program
In summary, we have prepared, in good yield, the enantiomerically pure $\mathrm{c}_{6} \mathrm{Phe}$ amino acids $\mathbf{3 a}$ and $\mathbf{3 b}$ by resolution of the corresponding diastereoisomeric dipeptides $7 \mathbf{a}$ and $\mathbf{7 b}$, and also the unsaturated dipeptides 11 a and 11 b . The peptides $\mathbf{7 b}$ and 11 b show type $\mathrm{I} \beta$ turn structures both in the solid state and in solution, suggesting that these compounds could constitute interesting building blocks for probing the relevance of $\beta$-turn secondary structures in peptides of biological significance and could be used for protein engineering. Moreover, the presence of the phenyl ring in the $i+2$ residue represents an additional advantage in the $\beta$ turn by virtue of having aromatic or hydrophobic amino acids in the third residue.

The results obtained in this paper complement the study reported by Toniolo et al. [3] concerning the stereochemically constrained peptides containing the Ac6c residue. These studies suggest that this residue should be an important component in the design of stereochemically rigid analogues of biologically active peptides, since this class of amino acid can be used to stabilise folded, helical structures or fully extended chains. In our case the cyclic analogues of Phe ( $\mathrm{c}_{6} \mathrm{Phe}$ ) could be used to stabilise folded ( $\beta$-turn) or extended chains, depending on whether $(1 S, 2 S)$ - or $(1 R, 2 R)$ - configurations are employed.

Further studies to incorporate the $\mathrm{c}_{6} \mathrm{Phe}$ amino acids in other peptides are in progress.

## Experimental section

Solvents were purified according to standard procedures. Analytical TLC was performed using Polychrom SI F254 plates. Column chromatography was performed using Silica gel 60 ( $230-400$ mesh). ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR spectra were recorded on a Bruker ARX-300 spectrometer. ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ spectra were recorded in $\mathrm{CDCl}_{3}$ with TMS as the internal standard and in $\mathrm{D}_{2} \mathrm{O}$-TFA with TMS as the external standard using a coaxial microtube (chemical shifts are reported in ppm on the $\delta$ scale, coupling constants in Hz ). Melting points were determined on a Büchi SMP-20 melting point apparatus and are uncorrected. Optical rotations were measured on a Perkin-Elmer 341 polarimeter in 1 and 0.5 dm cells of 1 and 3.4 mL capacity, respectively. Microanalyses were carried out on a Perkin-Elmer 240-C analyser and are in good agreement with the Calculated values.
( $\pm$ )-cis-2-Phenylcyclohexane-1-spiro-(4'[2'-phenyl-5'(4'H)-oxazolone]/ (6a,b)
A solution of $1 \mathrm{M} \mathrm{AlCl} 2_{2} \mathrm{Et}$ in hexane ( 3.75 mL ) was added to a solution of oxazolone 1 $(1.24 \mathrm{~g}, 5 \mathrm{mmol})$ in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$ under an inert atmosphere. After stirring the reaction mixture for 1 h at $0^{\circ} \mathrm{C}$, a solution of 1,3-butadiene ( $2.97 \mathrm{~g}, 55 \mathrm{mmol}$ ) in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 5 mL ), at the same temperature, was added dropwise and the mixture was stirred for a further 72 h at $0{ }^{\circ} \mathrm{C}$. The reaction was quenched by the addition of solid $\mathrm{Na}_{2} \mathrm{CO}_{3} \cdot 10 \mathrm{H}_{2} \mathrm{O}$, the precipitate was removed by filtration and the solvent was evaporated in vacuo. The residue was purified by silica gel column chromatography (hexane/ethyl acetate 9:1) to afford 994 $\mathrm{mg}(64 \%)$ of cycloadduct $\mathbf{2 a , b}$ as an oil. A solution of compound $\mathbf{2 a , b}$ ( $994 \mathrm{mg}, 3.5 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(15 \mathrm{~mL})$ was hydrogenated, using $10 \%$ palladium/carbon as a catalyst, at room temperature for 21 h . The catalyst and the solvent were removed to quantitatively give compound 6a,b as an oil.

${ }^{1} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}\right): \delta=1.60-2.18(\mathrm{~m}, 7 \mathrm{H}) ; 2.26-2.40(\mathrm{~m}, 1 \mathrm{H}) ; 3.17$ (dd, $1 \mathrm{H}, \mathrm{J}_{2 \mathrm{a}-3 \mathrm{a}}=13.2$, $J_{2 \mathrm{a}-3 \mathrm{e}}=3.6, \mathrm{H}_{2 \mathrm{a}}$ ); 7.12-7.20(m,5 H, Arom.); 7.41-7.58 (m, 3 H, Arom.); 7.86-7.92 (m, 2 H, Arom.).
${ }^{13} \mathrm{C}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}\right): \delta=21.3,26.1,28.1,35.2,50.1,73.7\left(\mathrm{C}_{1}, \mathrm{C}_{2}, \mathrm{C}_{3}, \mathrm{C}_{4}, \mathrm{C}_{5}, \mathrm{C}_{6}\right) ; 126.1$, 127.2, 127.8, 127.9, 128.5, 128.7 132.2, 139.5 (Arom); 160.6 ( $\mathrm{C}=\mathrm{N}$ ); 179.9 (COO).
(1R,2R)-[1-Benzamide-2-phenylcyclohexane-1-carboxamide]-(S)-phenylalanine cyclohexylamide (7a) and (1S,2S)-[1-Benzamide-2-phenylcyclohexane-1-carboxamide]-(S)phenylalanine cyclohexylamide (7b)

A solution of (S)-phenylalanine cyclohexylamide ( $1.60 \mathrm{~g}, 6.66 \mathrm{mmol}$ ) in $N$ -methylpyrrolidin-2-one (NMP) ( 3 mL ) was added to a solution of compound $\mathbf{6 a , b}$ ( 994 mg , 3.26 mmol ) in NMP ( 4 mL ) under an inert atmosphere. The reaction mixture was stirred for 48 h at $90^{\circ} \mathrm{C}$ and was allowed to cool to room temperature, and then poured onto a mixture of ice ( 25 g ), $1 \mathrm{~N} \mathrm{HCl}(25 \mathrm{~mL}$ ) and ethyl acetate ( 48 mL ). After stirring for 30 min the
mixture was allowed to separate into two phases, the organic layer was washed with $\mathrm{H}_{2} \mathrm{O}$ ( 2 x 20 mL ) and the aqueous phase was extracted with ethyl acetate $(2 \times 20 \mathrm{~mL})$. The combined organic phases were washed with brine ( $2 \times 20 \mathrm{~mL}$ ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and the solvent was removed to give the mixture of diastereoisomeric peptides, which were separated by silica gel column chromatography using hexane/ethyl acetate (1:1) as eluent. In this way 680 mg of peptide 7a (31\%) and 690 mg of peptide 7b (32\%) were obtained as colourless solids.
Peptide 7a: Anal. Calcd. for $\mathrm{C}_{35} \mathrm{H}_{41} \mathrm{~N}_{3} \mathrm{O}_{3} \mathrm{C}: 76.19, \mathrm{H}: 7.49, \mathrm{~N}: 7.62$; found $\mathrm{C}: 76.24, \mathrm{H}$ : 7.34, N: 7.53.

## Methyl (1R,2R)-1-benzamide-2-phenylcyclohexane-1-carboxylate (8a)

Compound $7 \mathrm{a}(540 \mathrm{mg}, 0.98 \mathrm{mmol})$ was dissolved in $\mathrm{MeOH}(12 \mathrm{~mL})$ and trifluoromethanesulphonic acid ( $0.26 \mathrm{~mL}, 2.94 \mathrm{mmol}$ ) was added at $0{ }^{\circ} \mathrm{C}$ under an inert atmosphere. The reaction was stirred for 48 h at reflux, cooled to room temperature and the solvent was removed in vacuo. The residue was suspended in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, filtered and the solvent evaporated. Compound $8 \mathbf{8}$ was purified by silica gel column chromatography using hexane/ethyl acetate ( $7: 3$ ) as eluent, giving $227 \mathrm{mg}(81 \%)$ of $8 \mathbf{a}$ as an oil.
Anal. Calcd. for $\mathrm{C}_{21} \mathrm{H}_{23} \mathrm{NO}_{3} \mathrm{C}: 74.75, \mathrm{H}: 6.87, \mathrm{~N}: 4.15$; found $\mathrm{C}: 74.86, \mathrm{H}: 6.80, \mathrm{~N}: 4.21$.
$[\alpha]^{25} \mathrm{D}\left(c=2.95, \mathrm{CHCl}_{3}\right)=-116.3$.
${ }^{1} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}\right): \delta=1.48-1.64(\mathrm{~m}, 2 \mathrm{H}) ; 1.66-1.76(\mathrm{~m}, 1 \mathrm{H}) ; 1.82-1.96(\mathrm{~m}, 2 \mathrm{H}) ; 2.05-$ 2.21 (m, 2 H ); 3.22-3.29 (m, $2 \mathrm{H}, \mathrm{H}_{2 \mathrm{a}}, \mathrm{H}_{6 \mathrm{e}}$ ); 3.51 (s, $3 \mathrm{H}, \mathrm{CO}_{2} \mathrm{CH}_{3}$ ); 6.22 (brs, $1 \mathrm{H}, \mathrm{NH}$ ); 7.14-7.20 (m, 2 H, Arom.); 7.22-7.50 (m, 6 H, Arom.); 7.62-7.70 (m, 2 H, Arom.).
${ }^{13} \mathrm{C}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}\right): \delta=20.7,25.7,26.7,37.0,49.6,51.8\left(\mathrm{C}_{2}, \mathrm{C}_{3}, \mathrm{C}_{4}, \mathrm{C}_{5}, \mathrm{C}_{6}, \mathrm{CO}_{2} \mathrm{CH}_{3}\right) ; 64.2$ (C1); 126.7, 127.4, 127.8, 128.5, 128.8, 131.4, 135.1, 140.0 (Arom); 167.7 (CONH); 173.3 $\left(\mathrm{CO}_{2} \mathrm{CH}_{3}\right)$.

## Methyl (1S,2S)-1-benzamide-2-phenylcyclohexane-1-carboxylate (8b)

In the same way as described above for compound $\mathbf{8 a}$, enantiomer $\mathbf{8 b}$ was obtained as an oil, in $88 \%$ yield starting from peptide 7 b ( $237 \mathrm{mg}, 0.43 \mathrm{mmol}$ ).
Anal. Calcd. for $\mathrm{C}_{21} \mathrm{H}_{23} \mathrm{NO}_{3} \mathrm{C}: 74.75, \mathrm{H}: 6.87, \mathrm{~N}: 4.15$; found $\mathrm{C}: 74.64, \mathrm{H}: 6.73, \mathrm{~N}: 4.26$. $[\alpha]^{25} \mathrm{D}\left(c=2.75, \mathrm{CHCl}_{3}\right)=+115.1$.
(1R,2R)-1-Amino-2-phenylcyclohexane-1-carboxylic acid (3a).
Compound 8a ( $100 \mathrm{mg}, 0.30 \mathrm{mmol}$ ) was dissolved in $10 \mathrm{~N} \mathrm{HCl}(30 \mathrm{~mL})$ and the mixture was heated under reflux for 48 h . The solvent was evaporated to leave a solid residue (the amino acid hydrochloride 9a), which was dissolved in $\mathrm{EtOH}(6 \mathrm{~mL}$ ) and then propylene oxide ( 2 mL ) was added. The mixture was heated under reflux for 1 h and partially precipitated. After removal of the EtOH , the residue was dissolved in distilled water ( 2 mL ) and eluted through a $\mathrm{C}_{18}$ reversed-phase Sep-pak cartridge which, after removal of water, gave $60 \mathrm{mg}(91 \%)$ of $\alpha$-amino acid 3a as a colourless solid [20].
Anal. Calcd. for $\mathrm{C}_{13} \mathrm{H}_{17} \mathrm{NO}_{2} \mathrm{C}: 71.19, \mathrm{H}: 7.82, \mathrm{~N}: 6.39$; found $\mathrm{C}: 71.28, \mathrm{H}: 7.75, \mathrm{~N}: 6.48$. $[\alpha]^{25} \mathrm{D}\left(c=6.00,0.1 \mathrm{M}\right.$ TFA in $\left.\mathrm{H}_{2} \mathrm{O}\right)=-21.1$.
(1S,2S)-1-Amino-2-phenylcyclohexane-1-carboxylic Acid (3b)
In a similar way to that described above for compound 3a, the free amino acid 3b was obtained as a colourless solid in $91 \%$ yield starting from compound $\mathbf{8 b}$ ( $100 \mathrm{mg}, 0.30 \mathrm{mmol}$ ) [20].
Anal. Calcd. for $\mathrm{C}_{13} \mathrm{H}_{17} \mathrm{NO}_{2} \mathrm{C}: 71.19, \mathrm{H}: 7.82, \mathrm{~N}: 6.39$; found $\mathrm{C}: 71.03, \mathrm{H}: 7.74, \mathrm{~N}: 6.25$. $[\alpha]^{25} \mathrm{D}\left(c=5.40,0.1 \mathrm{M}\right.$ TFA in $\left.\mathrm{H}_{2} \mathrm{O}\right)=+22.3$.

Allyl (1R,2R)-1-(benzyloxy)carbonylamino-2-phenylcyclohexane-1-carboxylate (10a)
To a stirred solution of amino acid hydrochloride 9 a ( $166 \mathrm{mg}, 0.65 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, under an inert atmosphere at $0^{\circ} \mathrm{C}$, was added TMS- $\mathrm{Cl}(0.21 \mathrm{~mL} 1.62 \mathrm{mmol})$. After heating for 1 h at reflux, the mixture was then cooled to $0^{\circ} \mathrm{C}$ and ${ }^{i} \operatorname{Pr}_{2} \mathrm{EtN}(0.31 \mathrm{~mL} 1.62 \mathrm{mmol})$ was added. The mixture was stirred for 1 h at reflux, recooled to $0^{\circ} \mathrm{C}$ and $\mathrm{Cbz}-\mathrm{Cl}(0.12 \mathrm{~mL} 0.84$ mmol ) was added. The mixture was allowed to warm up to room temperature and stirred for 24 h , and was then poured onto a mixture of ice $(5 \mathrm{~g}), 0.5 \mathrm{~N} \mathrm{HCl}(10 \mathrm{~mL})$ and ethyl acetate $(10 \mathrm{~mL})$. The organic layer was washed with $\mathrm{H}_{2} \mathrm{O}(2 \times 20 \mathrm{~mL})$ and brine ( $2 \times 20 \mathrm{~mL}$ ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and the solvent evaporated to give a residue corresponding
to Cbz protected $(1 R, 2 R)-\mathrm{c}_{6} \mathrm{Phe}$, which was used in the next step without purification. To a solution of the above residue in dry DMF ( 3 mL ), under an inert atmosphere at $0^{\circ} \mathrm{C}$, was addded DBU ( $0.17 \mathrm{~mL}, 0.78 \mathrm{mmol}$ ) and allyl bromide ( $0.12 \mathrm{~mL}, 1.3 \mathrm{mmol}$ ). The solution was stirred for 72 h at the same temperature and the solvent was removed to give an oily mixture, which was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$ and a mixture of ice ( 5 g ) and ethyl acetate ( 5 mL ) was added. After stirring for 5 min , the organic phase was washed with $\mathrm{H}_{2} \mathrm{O}(2 \times 20$ mL ) and brine ( $2 \times 20 \mathrm{~mL}$ ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and the solvent evaporated to afford the doubly protected amino acid, which was purified by silica gel column chromatography, eluting with hexane/ethyl acetate (1:1), to give $156 \mathrm{mg}(61 \%)$ of compound 10a.
Anal. Calcd. for $\mathrm{C}_{24} \mathrm{H}_{27} \mathrm{NO}_{4} \mathrm{C}: 73.26, \mathrm{H}: 6.92, \mathrm{~N}: 3.56$; found $\mathrm{C}: 73.19, \mathrm{H}: 6.84, \mathrm{~N}: 3.43$. $[\alpha]^{25} \mathrm{D}\left(c=2.60, \mathrm{CHCl}_{3}\right)=+20.2$.
${ }^{1} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}\right): \delta=1.51-2.19(\mathrm{~m}, 7 \mathrm{H}) ; 2.90-3.10\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{H}_{6 \mathrm{e}}\right) ; 3.20\left(\mathrm{dd}, 1 \mathrm{H}, J_{2 \mathrm{a}-3 \mathrm{a}}=\right.$ $13.2, J_{2 \mathrm{a}-3 \mathrm{e}}=3.3, \mathrm{H}_{2 \mathrm{a}}$ ); 4.38-4.52 (m, $2 \mathrm{H},-\mathrm{CH}=\mathrm{CH}_{2}$ ); 4.88 (brs, $1 \mathrm{H}, \mathrm{NH}$ ); 4.97-5.16 (m, 4 $\left.\mathrm{H}, \mathrm{O}-\mathrm{CH}_{2}-\mathrm{Ph}, \mathrm{O}-\mathrm{CH}_{2}-\mathrm{CH}=\mathrm{CH}_{2}\right) ; 5.58-5.73\left(\mathrm{~m}, 1 \mathrm{H},-\mathrm{CH}=\mathrm{CH}_{2}\right) ; 7.06-7.13(\mathrm{~m}, 2 \mathrm{H}$, Arom.); 7.23-7.38 (m, 8H, Arom.).

[17] Structures of 7a and 7b were built using the INSIGHT II molecular modelling program (version 2.1.0, San Diego: Biosym Technologies 1995 on an IRIS Silicon Graphics workstation). The ring conformations were initially fixed as those provided by another molecular mechanics calculations and NMR studies on related 2-phenylcyclohexanamino acids. The peptide bonds were orientated in a trans disposition. The CVFF and CFF91 force fields were used to optimize the molecular geometry.

[19] Crystal data of dipeptide 11b: $\mathrm{C}_{35} \mathrm{H}_{39} \mathrm{~N}_{3} \mathrm{O}_{3}$, monoclinic, space group $C 2 / c, a=9.113$ (2), $b=10.594$ (2), $c=32.541$ (7) $\AA, \mathrm{V}=3141.5$ (13) $\AA^{3}, \mathrm{Z}=4$. Mo- $K \alpha$ radiation, $\lambda=$ $0.71069 \AA$, graphite monochromator, $\omega / 2 \theta$ scan technique. A total of 6838 reflections were measured, and merged to 5533 unique reflections ( $\mathrm{R}_{\mathrm{merg}}=0.0322$ ). The structure was solved by direct methods (SHELXL 93). Least-squares (full matrix) refinement yielded R and $\mathrm{R}_{\mathrm{w}}$-values of 0.1599 and 0.1969 respectively. Complete data have been deposited at the Cambridge Crystallographic Data Centre.
[20] The ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR data for enantiomerically pure $\mathrm{c}_{6} \mathrm{Phe}$ amino acids are in accordance with those described by us in the literature: ref. 7
